Problem Statement Explanation :

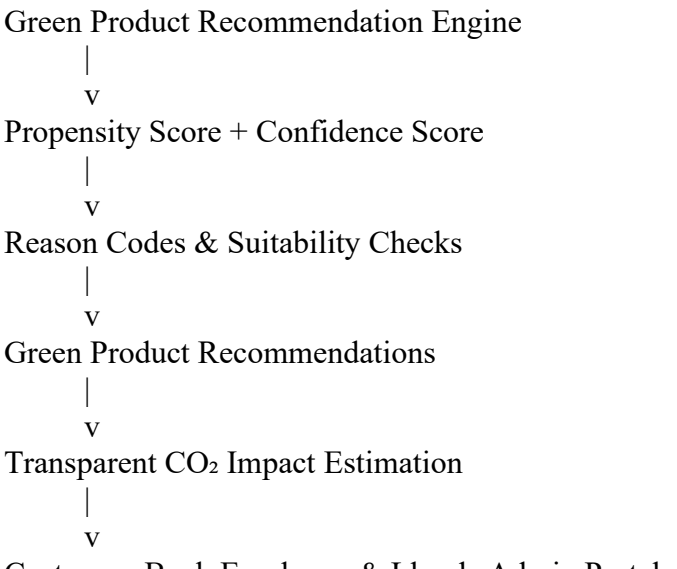

Banks find it difficult to identify customers who may be interested in green financial products using transaction data. They also need to understand why a product is recommended, how reliable the prediction is, and what environmental benefits it may provide. A solution is needed to recommend suitable green products, explain the reasons clearly, and estimate environmental benefits transparently.

Proposed Solution :

We propose an AI-powered Green Customer Insights Platform with three portals: Customer, Bank Employee, and Lloyd Admin. It analyses transactions to recommend suitable green financial products with propensity scores, confidence indicators, and reason codes. Customers can explore products, calculate loan repayments, and estimate CO_2 impact using a separate, transparent calculator. Bank employees can view their bank's customer insights and trends, while Lloyd Admin can monitor all associated banks and their customers through consolidated dashboards. Suitability safeguards ensure responsible recommendations.

Recommendation Pipeline

Customer Transaction Data

v
Customer Spending Pattern Analysis
|
v

Pipeline Explanation:

The platform processes customer transaction data and categories spending to identify relevant financial patterns. The recommendation engine uses these patterns to identify potentially suitable green financial products. Each recommendation includes a propensity score, a confidence indicator, and reason codes explaining why it was suggested. Suitability checks help prevent inappropriate recommendations. A separate, transparent calculator estimates potential environmental benefits using documented emission factors and clearly stated assumptions. The resulting insights are displayed through role-based portals with appropriate access controls.
